| $\mathrm{SO}_{3}$ | $s p^{2}$ |
| $\mathrm{C}_{2} \mathrm{H}_{2}$ | $s p$ |
| $\mathrm{C}_{2} \mathrm{H}_{4}$ | $s p^{2}$ |
| $\mathrm{CH}_{4}$ | $s p^{3}$ |
| $\mathrm{CO}_{2}$ | $s p$ |

2 (b)
$\mathrm{Mg}^{2+}$ is smaller thanNa ${ }^{+}$and thus, smaller is cation more is hydration energy.
3 (b)
Number of lone pair in $\mathrm{XeOF}_{4}$ is one (1). The structure of $\mathrm{XeOF}_{4}$ is given as follows:

One $\pi$-bond so remaining six electron pairs form an octahedron with one position occupied by a lone pair.
4 (d)
These are the factors on which van der Waals' forces depend.
5 (b)
It has $s p^{3} d^{3}$-hybridization with one lone pair on $\mathrm{X} e$.
6 (b)
Bond order $\propto \frac{1}{\text { Bond length }}$
BO of $\mathrm{NO}<\mathrm{BO}$ of $\mathrm{NO}^{+}$
$\therefore$ Bond length of NO is greater than the bond length of $\mathrm{NO}^{+}$.
7 (b)
Element with atomic number 20 is metal (Ca); it
will combine with non-metal.
8 (a)
A decrease in $s$-character increases bond length.
10 (b)
Calculated dipole moment,

$$
\begin{aligned}
\mu_{\text {cal }} & =2.0 \times 10^{-10} \mathrm{~m} \times 1.6 \times 10^{-19} \mathrm{C} \\
& =3.2 \times 10^{-29} \mathrm{C}-\mathrm{m} .
\end{aligned}
$$

Percentage of ionic character $=\frac{\mu_{\text {exp }}}{\mu_{\text {cal }}} \times 100$

$$
=\frac{5.12 \times 10^{-29}}{3.2 \times 10^{-29}} \times 100=16 \%
$$

11 (c)
$\mathrm{C}_{2} \mathrm{H}_{4}$ involves $s p^{2}$-hybridization on carbon atoms.
12 (b)
According to molecular orbital theory.
$\mathrm{F}_{2}(18)=\sigma 1 s^{2},{ }_{\sigma}^{*} 1 s^{2}, \sigma 2 s^{2},{ }_{\sigma}^{*} 2 s^{2}, \sigma 2 p_{z}^{2}, \pi 2 p_{x}^{2}$

$$
\approx \pi 2 p_{y, \pi}^{2 *} 2 p_{x}^{2} \approx{ }_{\pi}^{*} 2 p_{y}^{2}
$$

Bond order in $\mathrm{F}_{2}=\frac{N_{b-} N_{a}}{2}=\frac{10-8}{2}=1$
15 (a)
Bond formation is always exothermic. Compounds of sodium are ionic.
16 (d)
In case of water, five water molecules are attached together through four hydrogen bonding
(c)

Bond order of $\mathrm{NO}^{+}$, NO and $\mathrm{NO}^{-}$are $3,2.5$ and 2 respectively.
Bond energy $\propto$ bond order.
19 (a)
$\mathrm{F} X \mathrm{~F}$ angles of two types are present in $s p^{3} d$ hybrid orbitals. Since, $\mathrm{SF}_{4}$ shows $s p^{3} d$ hybridisation as follows, therefore, it exhibits two different $\mathrm{F} X \mathrm{~F}$ angles.

20 (c)
$s$-character $\propto$ bond angle
For $25 \% s$ character (as in $s p^{3}$ hybrid orbital), bond angle is $109.5^{\circ}$, for $33.3 \% s$ character (as in
$s p^{2}$ hybrid orbital), bond angle is $120^{\circ}$ and for $50 \% s$ character (as in $s p$ hybrid orbital ), bond angle is $180^{\circ}$.
Similarly, when the bond angle decreases below $1.9 .5^{\circ}$,thes -character will decrease accordingly Decreasing in angle $=120^{\circ}-109.5^{\circ}=10.5^{\circ}$
$\therefore$ Decrease in $s$-character $=33.3-25=8.3$
Actual decrease in bond angle $=109.5^{\circ}-105^{\circ}=$ $4.5^{\circ}$
$\therefore$ Expected decrease in $s$-character
$=\frac{8.3}{10.5} \times 4.5=3.56 \%$
Thus, the $s$-character should decrease by about $3.56 \%$, $i e, s$-character $=25-3.56=21.44 \%$
21 (b)

26 (d)
$\mathrm{PCl}_{5}$ has trigonal bipyramid geometry.
27 (b)
$\mathrm{SF}_{6}$ has octahedral geometry, $s p^{3} d^{2}$ hybridisation and bond angle is $90^{\circ}$

$\%$ of $d$-character $=\frac{2 \text { (no.of } d \text {-orbitals) }}{6 \text { (total hybridised orbitals) }} \times$ 100

$$
=33 \%
$$

So, $\mathrm{SF}_{6}$ are bond angle $=90^{\circ}$
and $\quad d$-character $=33 \%$.

There are two bond pairs and three lone pairs in the outer shell of central atom. To minimize the repulsive forces the three lone pairs occupy the equatorial position. The ion is therefore, linear in shape with a bond angle of exactly $180^{\circ}$.

48 (d)
In $\mathrm{BeCl}_{2}$, Be atom has incomplete octet.
49 (a)

In $\mathrm{CHCl}_{3}$, the resultant of $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{Cl}$ dipole oppose the resultant of two $\mathrm{C}-\mathrm{Cl}$ dipoles while in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, the resultant of $\mathrm{C}-\mathrm{H}$ dipoles adds to resultant of two $\mathrm{C}-\mathrm{Cl}$. In case $\mathrm{CH}_{3} \mathrm{Cl}$, the resultant of two $\mathrm{C}-\mathrm{H}$ dipole adds to the resultant of two C - Cl . In case $\mathrm{CH}_{3} \mathrm{Cl}$ the resultant of two $\mathrm{C}-\mathrm{H}$ dipoles add to the resultant of $\mathrm{C}-\mathrm{H}$ and $\mathrm{C}-\mathrm{Cl}$ dipoles.
Thus dipole moment of $\mathrm{CH}_{3} \mathrm{Cl}$ is highest among the given compounds. The molecule ( $\mathrm{CCl}_{4}$ ) again becomes symmetrical and dipole moment reduces

$\mathrm{XeF}_{2}$ molecule contains two bond pairs and three lone pairs in the outer-shell of central atom and thus its hybridisation is $s p^{3} d^{2}$ but to minimise the repulsive forces the three lone pairs occupy the equatorial position and the molecule becomes

Electron affinity decreases down the group, but ' 0 ' has small atomic size and $2 p$-orbital becomes very compact and already has 6 electrons, hence, there is a repulsive force among the already present and added electrons. Some of the energy evolved, due to addition of electron, is used to reduce the repulsion. Hence, the E.A. of 0 is less than $S$, so the order is $S>0>S e$.

## 319 (b)

Bond angle depends on the structure of molecule. If two molecules have same structure, then bond angle is decided by the electronegativity of central atom. Electrongeativity of central atom $\propto$ bond angle.
The bond angle of $\mathrm{H}_{2} \mathrm{~S}$ is less than $\mathrm{H}_{2} \mathrm{O}$ because S is less electronegative than $\mathrm{H}_{2} \mathrm{O}$.
Hence,

$\mathrm{BO}=\frac{N_{b-} N_{a}}{2}=\frac{10-4}{2}=3$
$\mathrm{NO}^{-}(16)=$
$\sigma 1 s^{2},{ }_{\sigma}^{*} 1 s^{2}, \sigma 2 s^{2},{ }_{\sigma}^{*} 2 s^{2}, \sigma 2 p_{x}^{2},\left(\pi 2 p_{y}^{2}=\pi 2 p_{z}^{2}\right)$,

$\mathrm{NO}^{+}(13) ; \mathrm{BO}=3$
$\mathrm{CN}^{-}(14) ; \mathrm{BO}=3$
$\mathrm{N}_{2}(14) ; B O=3$
Hence, bond order of $\mathrm{NO}^{-}$is different from that of CO.

399 (d)

The solubility of a compound mainly depend upon its hydration energy. If the hydration energy of a compound is greater than from its lattice enthalpy, then its is soluble in water. Thus, for solubility

For compounds $P$ and $R$ hydration enthalpy exceeds the lattice enthalpy, so they are soluble in water.

\approx \pi 2 p_{y}^{2},{ }_{\pi}^{*} 2 p_{x}^{1} \approx{ }_{\pi}^{*} 2 p_{y}^{1}
$$

$\mathrm{BO}=\frac{10-6}{2}=2$
$\mathrm{O}_{2}^{2-}(18)=\sigma 1 s^{2},{ }_{\sigma}^{*} 1 s^{2}, \sigma 2 s^{2},{ }_{\sigma}^{*} 2 s^{2}, \sigma 2 p_{z}^{2}, \pi 2 p_{x}^{2}$

$$
\approx \pi 2 p_{y}^{2},{ }_{\pi}^{*} 2 p_{x}^{2} \approx{ }_{\pi}^{*} 2 p_{y}^{2}
$$

$\mathrm{BO}=\frac{10-8}{2}=1$
$\mathrm{N}_{2}(14)=\sigma 1 s^{2},{ }_{\sigma}^{*} 1 s^{2}, \sigma 2 s^{2},{ }_{\sigma}^{*} 2 s^{2}, \pi 2 p_{x}^{2}$

$$
\approx \pi 2 p_{y}^{2}, \sigma 2 p_{z}^{2}
$$

$\mathrm{BO}=\frac{10-4}{2}=3$
Thus, bond order is highest for $\mathrm{N}_{2}$.

They produce ions in their aqueous solutions, so they are conducting in nature. Ethyl alcohol, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ being covalent in nature, does not produce any ion in aqueous solution. Hence, it is nonconducting in nature.

481 (b)
$\mathrm{KO}_{2}$ is an ionic compound.
In all the given compounds, anion is same $\left(\mathrm{Cl}^{-}\right)$, hence polarising power is decided by size and charge of cation. $\mathrm{Al}^{3+}$ with maximum charge and smallest size has maximum polarising power hence, $\mathrm{AlCl}_{3}$ is maximum covalent.

Lattice energy, $U=\frac{q_{1} q_{2}}{r^{2}}$
Since, interionic distances in CaO and NaCl are similar, (larger cation has smaller anion and vice versa) $r$ is almost the same. Therefore, lattice energy depends only on charge. Since, the magnitude of charge on $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions is same $i e$, unity and that on $\mathrm{Ca}^{2+}$ and $\mathrm{O}^{2-}$ ions is 2 each, therefore, the lattice energy of CaO is four times the lattice energy of $\mathrm{NaCl}, i e, 4 \mathrm{U}$
$s p \quad s p \quad s p^{2} \quad s p^{2}$
$\mathrm{CH} \equiv \mathrm{C}-\mathrm{CH}=\mathrm{CH}_{2}$

$=\frac{1}{2}(8-2)=3$
(ii) $\mathrm{N}_{2}^{+}$(13 electrons)
$=K K^{*}, \sigma 2 s^{2,}, \sigma s^{2}, \pi 2 p_{x}^{2} \approx \pi 2 p_{y}^{2}, \sigma 2 p_{z}^{1}$
Bond Order $=\frac{1}{2}(7-2)=2.5$
Since, bond dissociation energy $\propto$ bond order. Hence, bond dissociation energy of $\mathrm{N}_{2}$ is greater than that of the bond dissociation energy of $\mathrm{N}_{2}^{+}$.

Bond angles in $\mathrm{BeCl}_{2}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{SnCl}_{2}$ are $180^{\circ}, 107^{\circ}, 104.5^{\circ}$ and $119^{\circ}$ respectively. Also $\mathrm{H}_{2} \mathrm{~S}, \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2} \mathrm{Se}$ has $s p^{3}$-hybridization and bond angles of hydrides decreases down the group.
687 (d)
Liquid HCl does not from H -bonds
688 (a)
$\mathrm{O}_{2}$ has two unpaired electrons but are paired in
$\mathrm{O}_{2}^{2-}$.
689 (b)
In ethanol the oxygen of -OH group is bonded to the $s p^{3}$ hybridised carbon by a sigma bond. The $\mathrm{C}-\mathrm{O}-\mathrm{H}$ bond angle in ethanol is less than the tetrahedral angle $\left(109^{\circ}, 28^{\prime \prime}\right)$ due to larger repulsions between the lone pair of repulsions between the lone pairs of oxygen. Hence, it is $104^{\circ}$ in ethanol.

The atomic radii decreases along the period and increases down the gp.
(b)
$\mathrm{SiO}_{2}$ possesses giant molecular structure due to tetra valence and catenation nature of Si.
693 (d)
According to VSEPR theory the bond angle decreases with increase in the size of the valence shell of the central atom because electronegativity decreases. i.e., decreasing order of bond angles is $\mathrm{NH}_{3}>\mathrm{PH}_{3}>\mathrm{AsH}_{3}>\mathrm{SbH}_{3}$
694 (b)
Half-filled orbitals are more stable.
695 (a)
In $\mathrm{BrF}_{5}$ number of electrons $=6$ (1 $1 p+5 \mathrm{bp}$ )

So, the structure is supposed to be square pyramidal but will be distorted because of additional $l p-b p$ interaction.
Additional $l p-b p$ interaction reduced the all bond angle and do not let any angle to be $90^{\circ}$.
696 (b)
Ionisation energy decreases down the group and increases along the period.
697 (a)
Smaller is size of anion, lesser is its polarization, more is ionic nature, more is lattice energy.
698 (c)
Among the given species, the bond dissociation energy of $\mathrm{C}-0$ bond is minimum in case of $\mathrm{CO}_{3}^{2-}$ by which $\mathrm{C}-$ Obond become more weaker in $\mathrm{CO}_{3}^{2-}$ or the bond order of $\mathrm{CO}_{3}^{2-}(1.33)$ is minimum so, the bond become weaker

Bond order $=\frac{N_{b}-N_{a}}{2}=\frac{10-8}{2}=1$
It contains four completely filled antibonding molecular orbitals. Since, all the electrons are paired, $\mathrm{O}_{2}^{2-}$ is diamagnetic.
Peroxide ion is isoelectronic with argon, not with neon.

## Chlorobenzene

The hybridisation of ipso-carbon in chlorobenzene is $s p^{2}$.
709 (c)
Electronegativity difference between $\mathrm{N}(3,0)$ and $\mathrm{Cl}(3.0)$ is zero and hence, $\mathrm{N}-\mathrm{Cl}$ bonds are nonpolar. As a result, the overall dipole moment of $\mathrm{NCl}_{3}$ molecule and its direction is just the dipole moment of the lone pair of electrons

On the other hand, $\mathrm{N}-\mathrm{Br},(3.0-2.8), \mathrm{N}-\mathrm{I}(3.0-$ $2.5)$ and $\mathrm{N}-\mathrm{H}(3.0-2.1)$ are polar and hence, contribute towards the overall dipole moment of the respective moleculas. Since, the EN difference is higher in case of $\mathrm{N}-\mathrm{H}$ bonds, therefore, $\mathrm{NH}_{3}$ has the higher dipole moment
710 (c)
$\mathrm{CHCl}_{3}$ molecule has largest dipole moment among the given species.
711 (d)
In $\mathrm{O}_{2}$, there are two electrons in antibonding orbitals. Removal of one electron from the $\mathrm{O}_{2}$ molecular gives $\mathrm{O}_{2}^{+}$in which the number of antibonding electrons is one less and hence, BO increases. Thus, removal of the electron from $\mathrm{O}_{2}$ stabilized the molecule
712 (a)
$\mathrm{Mg}^{2+}$ is a smaller cation in these. Smaller is cation more is hydration energy.

713 (b)
Hydrogen bonding $\propto$ electronegativity
714 (c)
Larger is anion, more is its polarization.
715 (c)
NaF is more ionic; F is smallest anion among all and thus, least polarized.
716 (a)

Hence, In acetylene, there are $3 \sigma$ and $2 \pi$ bond.
717 (d)
+4 ionic state is not possible for head with iodide because $\mathrm{I}^{-}$reduces $\mathrm{Pb}^{4+}$ to $\mathrm{Pb}^{2+}$.
718 (a)
The $\mathrm{C}-\mathrm{C}$ bond length in $s p^{3}$ hybridisation is greater than $s p^{2}$ hybridisation due to large size of $p$-orbitals.
In diamond $s p^{3}$ hybridisation is present while in graphite, naphthalene and fullerene $s p^{2}$ hybridisation is present therefore the $\mathrm{C}-\mathrm{C}$ bond length is maximum in diamond.
720 (d)
$\mathrm{SiO}_{2}$ structure is definite.

722 (a)
We know that the shape of $\mathrm{IF}_{7}$ (molecule) is
pentagonal bipyramidal because central atom I have $s p^{3} d^{3}$ hybridisation.
723 (a)
C - C bond length $=1.54 \AA$
$\mathrm{C}=\mathrm{C}$ bond length $=1.34 \AA$
$\mathrm{C} \equiv \mathrm{C}$ bond length $=1.20^{\circ} \AA$
Thus, correct decreasing order C to C bond lengths is
IV $>$ III $>$ I $>$ II
724 (b)
Due to larger difference in electronegativity.
725 (d)
Both O and S belong to same group but $\mathrm{H}_{2} \mathrm{O}$ is a liquid while $\mathrm{H}_{2} \mathrm{~S}$ is a gas. This can be explained on the basis of electronegativity. In water due to the high electronegativity of oxygen hydrogen bonds are formed. As a result the molecules of $\mathrm{H}_{2} \mathrm{O}$ get associate together, hence water exists as a liquid at room temperature. On the other hand, the electronegativity of S is less and therefore, hydrogen bonding in $\mathrm{H}_{2} \mathrm{~S}$ is almost negligible. As a result of which molecules of $\mathrm{H}_{2} \mathrm{~S}$ are not associated and $\mathrm{H}_{2} \mathrm{~S}$ exsists as a gas at room temperature.
726 (d)
$\mathrm{S}=\mathrm{C}=\mathrm{S}$.
727 (d)
The bond angles in $s p^{3}, s p^{2}$ and $s p$-hybridization are $109^{\circ}, 120^{\circ}$ and $180^{\circ}$ respectively.
728 (d)
In $\mathrm{ClO}_{3}^{-}, \mathrm{Cl}$ is central atom, it is $s p^{3}$ hybrid and on it one lone pair of electrons (free pair of electrons) is present.

In $\mathrm{XeF}_{4}$, Xe is central atom it is $s p^{3} d^{2}$ hybrid and on it two lone pair of electrons are present.

Square planar
In $\mathrm{SF}_{4}, \mathrm{~S}$ is central atom and $s p^{3} d$-hybridised and
on it one lone pair of electrons is present.

Irregular tetrahedral
In $\mathrm{I}_{3}^{-}$, I is central atom and it is $s p^{3} d$ hybridised and on it three lone pair of electrons are present.

Linear shape

Seven atoms of fluorine are covalently bonded with iodine.

Intermolecular hydrogen bonding is found in (HF) ${ }_{n}$ due to higher electronegativity of fluorine atoms.

Hydrogen bonding
Hydrogen bonding is helpfull in the association of HF molecule, so HF is found in liquid form.
732 (c)
A species is said to be diamagnetic if it has all electrons paired

| $\mathrm{He}_{2}^{+}$ | 3 | $\sigma 1 s^{2}{ }_{\sigma} 1 s^{1}$ | Paramagnetic |

733 (b)
This give rise to polarity in bonds.
First electron affinity is energy releasing process.
$\mathrm{Li}^{-}: 1 s^{2}, 2 s^{2} ; \mathrm{Be}^{-}: 1 s^{2}, 2 s^{2}, 2 p^{1}$; in Li, addition of electron has taken place in 2 s orbital; in $\mathrm{Be}^{-}$, addition of electron has taken place in $2 p$ orbital loosing its $2 s$ completely filled configuration.
$E A_{1}$ for Be is more positive than $E A_{1}$ for Li . Thus $\mathrm{Be}^{-}$is least stable.

736 (d)
Bond energy for $\mathrm{C}-\mathrm{C}, \mathrm{N}-\mathrm{N}, \mathrm{H}-\mathrm{H}$ and $\mathrm{O}-\mathrm{O}$ are : $\mathrm{H}-\mathrm{H}>\mathrm{C}-\mathrm{C}>\mathrm{N}-\mathrm{N}>\mathrm{O}-\mathrm{O}$.
737 (b)
The number of lone pair in $\mathrm{XeOF}_{4}$ is one (1). The structure of $\mathrm{XeOF}_{4}$ is given as follows

740 (c)
$\mathrm{CCl}_{4}$ has $s p^{3}$-hybridization giving regular tetrahedron geometry. In others the geometry is little distorted inspite of $s p^{3}$-hybridization due to different atoms on the vertices of tetrahedron.
741 (b)

Trigonal bipyramidal shape of $\mathrm{PCl}_{5}$

742 (a)
Electronegativity difference in two atoms involved in bonding is a measure of polarity in molecule.
743 (c)
$\equiv \mathrm{C}$ - has $2 \sigma$-and $2 \pi$ - (thus, $s p$-hybridization); $-\mathrm{CH}=$ has $3 \sigma$ - and $1 \pi$ - (thus, $s p^{2}$-hybridization). Remember hybridized orbitals do not form $\pi$ bonds.
744 (b)
F has 7 electrons in its valence shell. Thus, to attain stability, it should have lost one electron.

In $\mathrm{O}_{2}^{2-}, 8$ electrons are present in antibonding orbitals
$\sigma 1 s^{2}, \sigma^{*} 1 s^{2}, \sigma 2 s^{2}, \sigma^{*} 2 s^{2}, \sigma 2 p_{x}^{2}\left[\begin{array}{c}\pi 2 p_{y}^{2} \\ \pi 2 p_{z}^{2}\end{array}\right],\left[\begin{array}{c}\pi^{*} p_{y}^{2} \\ \pi^{*} 2 p_{z}^{2}\end{array}\right]$
746 (a)
$\mathrm{CH}_{3}^{+}$possesses $s p^{2}$-hybridization.
747 (a)
No doubt $\mathrm{NH}_{3}$ and $\mathrm{BF}_{3}$ have $s p^{3}$ (pyramidal) and $s p^{2}$ (coplanar) hybridization respectively having one lone pair of electron on N atom which is responsible for pyramidal shape of $\mathrm{NH}_{3}$ inspite of $s p^{3}$ hybridization. However, as soon as it is coordinated to $\mathrm{BF}_{3}$, both attain tetrahedral geometry and acquire $s p^{3}$-hybridization.
748 (b)

Thus, every P -atom is linked to 3 oxygen atoms.

750 (d)
Bond energy $\propto$ Bond order
751 (a)
In $\mathrm{XeF}_{6}$, the oxidation state of Xe is +6 . The shape of $\mathrm{XeF}_{6}$ should be pentagonal bipyramid due to $s p^{3} d^{3}$ hybridisation but due to the presence of one lone pair at one trans position its shape becomes distorted octahedral.

$\mathrm{Cl}-\mathrm{P}-\mathrm{Cl}$ bond angles in $\mathrm{PCl}_{5}$ molecule are $120^{\circ}$ and $90^{\circ}$. $\mathrm{PCl}_{5}$, having $s p^{3} d$ hybridised P atom (trigonal bipyramidal geometry) has two types of bonds; axial and equatorial. The two types of bond have different bond lengths $1,2,3$ and 4 equatorial bonds and 4,5 axial bonds.

772 (d)
The ionic radius increases down the group.
773 (b)
The formula of $M X_{3}$ shows the presence of $3 \sigma$ bonds. Since, it has T-shape geometry, it must contain 2 lone pairs as

774 (a)

Bond order $=\frac{10-4}{2}=3$
$\mathrm{N}_{2}^{+}(7+7-1=13)$ $=\sigma 1 s^{2}, \sigma^{*} 1 s^{2}, \sigma 2 s^{2}, \sigma^{*} 2 s^{2}, \pi 2 p_{x}^{2}$
$=\pi 2 p_{y}^{2}, \sigma 2 p_{\pi}^{1}$ (paramagnetic)

Bond order $=\frac{9-4}{2}=2.5$
Since, $N_{2}^{+}$has less bond, then N - Nbond gets
weak
$\mathrm{O}_{2}(8+8=16)$
$=\sigma 1 s^{2}, \sigma^{*} 1 s^{2}, \sigma 2 s^{2}, \sigma^{*} 2 s^{2}, \sigma 2 p_{z}^{2}, \pi 2 p_{x}^{2}$
$\approx \pi 2 p_{y}^{2}, \pi^{*} 2 p_{x}^{1} \approx \pi^{*} 2 p_{y}^{1}$
Bond order $=\frac{10-6}{2}=2$
$\mathrm{O}_{2}^{+}(8+8-1=15)$
$=\sigma 1 s^{2}, \sigma^{*} 1 s^{2}, \sigma 2 s^{2}, \sigma^{*} 2 s^{2}, \sigma 2 p_{z}^{2}, \pi 2 p_{x}^{2}$
$\approx \pi 2 p_{y}^{2}, \pi^{*} 2 p_{x}^{1}$
Bond order $=\frac{10-5}{2}=2.5$
Thus, in the formation of $\mathrm{O}_{2}^{+}$from
$\mathrm{O}_{2}$, paramagnetism decreases but the bond order increases

25. Between $\mathrm{NH}^{3}$ and $\mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{2} \mathrm{O}$ has smaller bond angle due to presence of two lone pair of electrons causing more repulsion among electrons as compared of $\mathrm{NH}^{3}$ which has only one lone pair of electron.

(a) $\mathrm{NH}_{3}+\mathrm{H}^{+} \rightarrow \mathrm{NH}_{4}^{+}$
$(3 b p+1 l p) \quad\left(4 b p \Rightarrow s p^{3}\right.$ hybridisation $)$
$\Rightarrow s p^{3}$ hybridisation)
(b) $\mathrm{BF}_{3}+\mathrm{F}^{-} \rightarrow \mathrm{BF}_{4}^{-}$
(3bp+sp2 hybridisation)
( $4 b p \Rightarrow s p^{3}$ hybridisation)
(c) $\mathrm{H}_{2} \mathrm{O}+\mathrm{H}^{+} \rightarrow \mathrm{H}_{3} \mathrm{O}^{+}$
$(2 b p+2 l p$
$(3 b p+11 p$
$\Rightarrow s p^{3}$ hybridisation) $\Rightarrow s p^{3}$ hybridisation)
(d) $\mathrm{CH} \equiv \mathrm{CH}+2 \mathrm{H}_{2} \rightarrow \mathrm{CH}_{3}-\mathrm{CH}_{3}$
$s p s p \quad s p^{3} s p^{3}$
Hence, reaction given in option (b) involves the change of hybridisation from $s p^{2}$ to $s p^{3}$.

963 (c)
Potash alum is a double salt.
Potash alum, $\mathrm{K}_{2} \mathrm{SO}_{4} . \mathrm{Al}_{\mathrm{x}}\left(\mathrm{SO}_{4}\right)_{3} .24 \mathrm{H}_{2} \mathrm{O}$ (given)

| Ions | Al | $\mathrm{SO}_{4}$ |
| :--- | :--- | :--- |
| Valency | +3 | -2 |

Therefore, $\mathrm{Al}_{3}\left(\mathrm{SO}_{4}\right)_{3}$ is compound of $\mathrm{Al}^{3+}$ and $\mathrm{SO}_{4}^{2-}$.
On comparing, $x=2$
Hence, formula of potash alum is

$$
=\mathrm{K}_{2} \mathrm{SO}_{4} \cdot \mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 24 \mathrm{H}_{2} \mathrm{O}
$$

${ }_{\pi}^{*} 2 p_{y}^{2}={ }_{\pi}^{*} 2 p_{z}^{1}$
965 (c)
HCl exists as $\mathrm{H}^{\delta+}-\mathrm{Cl}^{\delta-}$ due to difference in electronegativity of H and Cl .
966 (b)
Outer shell electrons are referred as valence electrons.
967 (d)
Bond order $\propto$ stability
Species Bond order
$\mathrm{O}_{2}^{+} \quad 2.5$
$\mathrm{O}_{2}$
2.0
$\mathrm{O}_{2}^{-} \quad 1.5$
Hence, the order of stability is
$\mathrm{O}_{2}^{+}>\mathrm{O}_{2}>\mathrm{O}_{2}^{-}$

$\mathrm{IF}_{5}$ is square pyramid ( $s p^{3} d^{2}$-hybridisation in I);
$\mathrm{PCl}_{5}$ is trigonal bipyramid ( $s p^{3} d$-hybridisation in P).

970 (d)
Characteristics of bond order concept.

972 (b)
Bond energy of $\mathrm{Cl}_{2}$ is highest among all halogen molecules. B.E. of $\mathrm{F}_{2}, \mathrm{Cl}_{2}, \mathrm{Br}_{2}, \mathrm{I}_{2}$ are $37,58,46$ and $36 \mathrm{kcal} \mathrm{mol}^{-1}$ respectively.

## 974 (a)

Bond length $\propto \frac{1}{\text { Bond order }}$
$\mathrm{NO}^{-}=16 e^{-}$
$=\sigma 1 s^{2},{ }_{\sigma}^{*} 1 s^{2}, \sigma 2 s^{2},{ }_{\sigma}^{*} 2 s^{2}, \sigma 2 p_{x}^{2}, \pi 2 p_{y}^{2}$
$=\pi 2 p_{z}^{2},{ }_{\pi}^{*} 2 p_{y}^{1}={ }_{\pi}^{*} 2 p_{z}^{1}$

$$
\begin{aligned}
\text { BO } & =\frac{N_{b}-N_{a}}{2} \\
& =\frac{10-6}{2}=2
\end{aligned}
$$

Similarly BO of $\mathrm{NO}^{+}$will be calculated as $\mathrm{NO}^{+}=14 e^{-}$
$\mathrm{BO}=\frac{10-4}{2}=3$
$\mathrm{CN}^{-}=14 e^{-}, \mathrm{BO}=3$
$\mathrm{CN}^{+}=13 e^{-}, \mathrm{BO}=\frac{9-4}{2}=2.5$
Bond order is least for $\mathrm{NO}^{-}$. So, its bond length is highest.
975 (c)
$\mathrm{CsBr}_{3} \rightarrow \mathrm{Cs}^{+}+\mathrm{Br}_{3}^{-}$
976 (c)
