 $C_2H_5O^-$ will attract the proton from phenol converting the later into phenoxide ion. This would then make nucleophilic attack on the methylene carbon of alkyl iodide, but $C_2H_5O^-$ is in excess $C_2H_5O^-$ is better nucleophile than $C_6H_5O^-$ (phenoxide) ion since while in the former the negative charge is localised over oxygen and in the later it is delocalised over the whole molecular frame work. So, it is $C_2H_5O^-$ ion that would make nucleophilic attack at ethyl iodide to give diethyl ether (Williamson's synthesis).

When an electron attracting group (like $-NO_2$, -CI) is attached to the phenol ring, it stabilises the negative charge on the oxygen of phenoxide ion. Due to this reason acidic character of phenol increases. But when an electron donating group (like $-CH_3$) is attached to the phenol ring, it destabilises the ring and hence, acidic character of phenol decreases. Thus, the correct order of acidic character is p- nitrophenol > p-chlorophenol > p-henol > o-cresol.

Assertion - Reasoning Type

This section contain(s) 0 questions numbered 1 to 0. Each question contains STATEMENT 1(Assertion) and STATEMENT 2(Reason). Each question has the 4 choices (a), (b), (c) and (d) out of which **ONLY ONE** is correct.

- a) Statement 1 is True, Statement 2 is True; Statement 2 is correct explanation for Statement 1
- b) Statement 1 is True, Statement 2 is True; Statement 2 is not correct explanation for Statement 1
- c) Statement 1 is True, Statement 2 is False
- d) Statement 1 is False, Statement 2 is True

1

- **Statement 1:** Benzoic acid is stronger acid than phenol
- **Statement 2:** Resonating structures of phenoxide ion has negative charge on less electronegative carbon atom

2

Statement 1:

Dehydration of ${\rm CH_3CH_2CHCH_3}$ gives ${\rm CH_3CH_2CH=CH_2}$ as the minor product ad ${\rm CH_3CH=CHCH_3}$ as the major product

Statement 2:

3

- **Statement 1:** When glycerol is heated with hydrogen iodide, only allyl iodide is formed

: HINTS AND SOLUTIONS :

1 **(a)**

In phenoxide ion all the resonating structures except one have negative charge on less electronegative carbon atom while in benzoate ion, both the resonating forms have negative charge on more electronegative oxygen atom

3 **(d)**

When glycerol is heated with a small amount of HI, allyl iodide is fromed

CH₂OH
$$\longrightarrow$$
 CH₂ \parallel CHOH + 3HI \longrightarrow CH₂ \parallel CH \longrightarrow CH₂I \longrightarrow CH₂I glycol allyl iodide

When glycerol is heated with a large amont of HI, the allyl iodide first formed is reduced to propene, which in presence of excess of HI forms isopropyl iodide

4 (h)

Due to the presence of lone pairs of electrons on the oxygen atom, ethers behave as Lewis bases. They dissolve in acids like conc $\rm H_2SO_4$ and conc HCl to form oxonium salts

$$R - O - R + HCl \rightarrow [R_2OH]^+Cl$$

5 **(a)**

The high polarisation of O — H bond in alcohols gives rise to intramolecular hydrogen bonding, *ie*, molecules are brought nearer to each other and held together by attractive forces. No such hydrogen bonding exists in alkanes
