$\mathrm{CHCl}_{3} \xrightarrow{\mathrm{HOH}} \mathrm{CH}(\mathrm{OH})_{3} \rightarrow \mathrm{HCOOH}$
2

The keto-ester ( $A$ ) does not give haloform reaction inspite of the presence of $\mathrm{CH}_{3} \mathrm{CO}$ - group in it. The reason is the presence of active methylene group (ie, $-\mathrm{CH}_{2}-$ ), which prevents the conversion of $\mathrm{CH}_{3} \mathrm{CO}-$ to $\mathrm{CX}_{3} \mathrm{CO}-$
3 (c)

$\mathrm{LiAlH}_{4}$ is a strong reducing agent, which reduces carboxylic acids to corresponding primary alcohols as well as alkyl halide to alkenes, but donot reduce double bond

The strength of carboxylic acid depends upon the nature of the electron withdrawing halogen atom. Greater the electron withdrawing influence of the halogen atom stronger will be the acid. The electron withdrawing effect of the halogen decreases as

Acetic acid is obtained by the oxidation of ethanol with alkaline $\mathrm{KMnO}_{4}$.

The acid amides are amphoteric in nature. In amides, the lone pair of electrons on N atom remains delocalised (in resonance) with ( $\mathrm{C}=0$ ) group.
$\therefore$ Amides are not much basic but infact they are amphoteric in nature.

303 (d)

304 (a)

306 (b)
This reaction is an example of rearrangement, ie, migration of alkyl group from carbon to adjacent nitrogen atom and the group which is trans to the leaving group ( -OH group) migrates leading to the formation of resonance stabilised imine

310 (c)
In phenyl magnesium bromide $\binom{\delta-\delta+}{\mathrm{Ph} \mathrm{Mg} \mathrm{Br}}^{\delta-} \cdot \mathrm{Ph}$ is attached with that C-atom of carbonyl group which have low electron density (higher electropositive charge)
In carbonyl compounds, aldehydes are more reactive

towards nucleophile in nucleophilic addition reaction because in ketones alkyl groups(due to $+I$ effect) decrease the electropositive charge of carbon of carbonyl group. Hence attraction of nucleophile decreases. Moreover in the tetrahedral intermediate aldehyde have less steric repulsion than ketones and also the aldehyde increases the negative charge on oxygen less in comparison of ketones.

Thus, on the basis of above reason the order of reactivity of acetone(I), acetaldehyde (II) and benzaldehyde (III) with PhMgBr is

$$
\text { II }>\text { I }>\text { III }

## (b)

The kjeldahl's method is based on the fact that nitrogen of an organic compound is quantitatively converted to $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ on heating with $\mathrm{H}_{2} \mathrm{SO}_{4}$ (conc.). The $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}$ is then treated with KOH to liberate $\mathrm{NH}_{3}$, which is absorbed in $\mathrm{H}_{2} \mathrm{SO}_{4}$ to obtain $\%$ of N .

Carbonyl compound reacts with Grignard reagent following nucleophilic addition. More is +ve charge on $\mathrm{C}^{+}$centre of carbonyl group, easier is nucleophilic attack.

In $p$-nitrobenzoyl chloride, $-\mathrm{NO}_{2}$ group has a $-I$ and $-R$-effect and this is greater from the $p$ position than from $m$-or $o$-positions. Thus, $-\mathrm{NO}_{2}$ group reduces the electron density at the carbon atom attached to - Cl atom and facilitate its releasing and hydrolysis of benzoyl chloride

Whereas, $\mathrm{CH}_{3} \mathrm{O}$-group has a strong $+R$-effect and a weak - $I$-effect. At $p$-position $\mathrm{CH}_{3} \mathrm{O}$-group exerts its strong $+R$ effect. As a result, electron density at C -atom attached to -Cl atom increases and the cleavage of $\mathrm{C}-\mathrm{Cl}$ bond becomes difficult. Hence, the order of reactivity of hydrolysis of acid chlorides:

An aqueous solution of sodium periodate and a trace of potassium permanganate is known as Lemieux reagent. The alkene is oxidized to cisdiol, which is cleaved by periodate to aldehydes and/or ketones. Aldehydes are further oxidized by $\mathrm{KMnO}_{4}$ to acids

This is better for both determining the position of double bond and for preparing carbonyl compounds, because in this method, formaldehyde is usually obtained from terminal alkene, instead of producing $\mathrm{CO}_{2}$ and water

Alkali used is $\mathrm{Ba}(\mathrm{OH})_{2}$.
954 (c)

## CHEMISTRY

## : HINTS AND SOLUTIONS :

1 (c)
The anion left after the removal of $\alpha$-hydrogen is stabilised by resonance effect

2 (b)
The carboxyl group $(-\mathrm{COOH})$ is an electron withdrawing group and therefore deactivates the benzene ring towards electrophilic attack. Therefore, benzoic acid doe not give FriedelCraft's reaction

3 (a)
In formate ion, resonance gives rise to identical bond lengths

4 (d)
Highly branched carboxylic acids are less acidic than unbranched acids. The $+I$ effect of alkyl groups in branched one increases the magnitude of negative group. The $-\mathrm{COO}^{-}$group is shielded from solvent molecules and can't be stabilised by solvation as effectively as in unbranched carboxylic acids

5 (c)
Formic acid is stronger than acetic acid

(b)

Both carbon and oxygen are non-metals and try to
complete their octet. In $R-\mathrm{C} \equiv \mathrm{O}^{+}$each has complete octet, whereas in $R-\mathrm{C}^{+}=0$, carbon atom has incomplete octet

## (c)

$\mathrm{CH}_{3} \mathrm{CO}$ - group in acetophenone being electron withdrawing reduces the electron-density at the benzene ring, thereby preventing further electrophilic substitution

8 (b)
The high degree of polarity in $\mathrm{H} X$ as well as in carbonyl bond shows the easy addition of $\mathrm{H} X$ on carbonyl bond but as soon as the addition products are formed, the products loses to $\mathrm{H} X$ to show the backward reaction
$\mathrm{CH}_{3}^{-}$ion is much stronger nucleophile due to $+I$

10 (d)
Both furmaric acid and maleic acid have two ionisable protons. At first sight, since the structures are identical, it might have been expected that the ionisation constants would be the same. However,
