During rusting, oxidation of iron takes place, i.e., it acts as anode. Hence, coating/connecting iron with metal of lower reduction potential (in comparison to iron) is the best way to prevent its rusting. In this process, the metal with low reduction potential undergoes oxidation (i.e. acts as anode) while iron acts as cathode. (Cathodic protection)
Use of saline water accelerates the process of rusting thereby increasing the electric conduction of electrolyte solution formed on the metal surface.

$\therefore \mathrm{CuSO}_{4}$ reacts with Zn and Fe placed above it.
$\mathrm{CuSO}_{4}+\mathrm{Fe} \rightarrow \mathrm{FeSO}_{4}+\mathrm{Cu}$
$\mathrm{CuSO}_{4}+\mathrm{Zn} \rightarrow \mathrm{ZnSO}_{4}+\mathrm{Cu}$

268 (a)
The required reaction $\left(\mathrm{Cu}^{2+}+\mathrm{Cu} \rightarrow 2 \mathrm{Cu}^{+}\right)$can be obtained by using the following reactions
$\mathrm{Cu}^{2+}+e^{-} \rightarrow \mathrm{Cu}^{+}, E^{\circ} \mathrm{Cu}^{2+} / \mathrm{Cu}^{+}=0.15 \mathrm{~V}$
$\mathrm{Cu}^{2+}+2 e^{-} \rightarrow \mathrm{Cu}, E^{\circ} \mathrm{Cu}^{2+} / \mathrm{Cu}=0.34 \mathrm{~V}$
Multiplying Eq. (i) by 2, we get
$2 \mathrm{Cu}^{2+}+2 e^{-} \rightarrow 2 \mathrm{Cu}^{+}$,
$\Delta G_{1}=-n F E=-2 \times F \times 0.15$
$\mathrm{Cu}^{2+}+2 e^{-} \rightarrow \mathrm{Cu}$
$\Delta G_{2}=-n F E=-2 \times F \times 0.34$
Subtract the Eq. (iv) from Eq. (iii)
$\mathrm{Cu}^{2+}+\mathrm{Cu} \rightarrow 2 \mathrm{Cu}^{+}$
$\Delta G_{3}=-n F E=-1 \times F \times E^{\circ}$
Also $\Delta G_{3}=\Delta G_{1}-\Delta G_{2}$
$\therefore-1 F E^{\circ}=(-2 F \times 0.15)-(-2 F \times 0.34)$
$E^{\circ}=-0.38$
This is the value for the reaction
$\mathrm{Cu}^{2+}+\mathrm{Cu} \rightarrow 2 \mathrm{Cu}^{+}$
But the given reaction is just reverse of it
$\therefore E_{\text {cell }}$ for given reaction $=+0.38 \mathrm{~V}$
269 (d)
According to Kohlrausch's law

$\Lambda_{\mathrm{HCl}}^{\circ}=\Lambda_{\mathrm{H}^{+}}^{\circ}+\Lambda_{\mathrm{Cl}^{-}}^{\circ} \quad$..(ii)
$\Lambda_{\mathrm{CH}_{3} \mathrm{COONa}}^{\circ}=\Lambda_{\mathrm{CH}_{3} \mathrm{COO}^{-}}^{\circ}+\Lambda_{\mathrm{Na}^{+}}^{\circ} \ldots$ (iii)
Thus, on adding (ii) and (iii), if $\Lambda_{\mathrm{Na}^{+}}^{\circ}$ and $\Lambda_{\mathrm{Cl}^{-}}^{\circ}$ are subtracted we can obtained the value of $\Lambda_{\text {HOAc. }}^{\circ}$.
Thus, additional value required is $\Lambda_{\mathrm{NaCl}}^{\circ}$.

The PH of 0.1 M HCl and 0.1 M acetic acid is not the same, because HCl is a strong acid, so its pH is more and $\mathrm{CH}_{3} \mathrm{COOH}$ is a weak acid, so its pH is less

$E_{2}=E^{\circ}-\frac{0.059}{1} \log \left[\mathrm{H}^{+}\right]_{2}$
on adding (also $E_{\mathrm{H}}^{\circ}=0$ )
$E_{1}+E_{2}=-\frac{0.059}{1}\left[\log \left(\mathrm{H}^{+}\right)_{1}+\log \left(\mathrm{H}^{+}\right)_{2}\right]$
Now for $\mathrm{CH}_{3} \mathrm{COOH}=\mathrm{CH} 3 \mathrm{COO}^{-}+\mathrm{H}^{+}$

$$
\begin{aligned}

$4 e^{-}+4 \mathrm{H}^{+} \rightarrow 2 \mathrm{H}_{2}$
$\therefore n=4$,
So, 4 F charge liberates $=1 \mathrm{~mol}=22.4 \mathrm{dm}^{3}$

$\therefore 1 \mathrm{~F}$ charge will liberate $=\frac{22.4}{4}=5.6 \mathrm{dm}^{3}$ oxygen
343 (a)

$E_{\text {cell }}^{\circ}=1.470 \mathrm{~V}$
$E_{\text {cell }}^{\circ}=E_{\mathrm{H}^{+} / \mathrm{H}_{2}}^{\circ}-E_{M / M^{2+}}^{\circ}$
$E^{\circ}{ }_{M} / M^{2+}=-1.470$
So, $E_{M^{2+} / M}^{\circ}=1.470 \mathrm{~V}$
345 (c)
$E_{\text {cell }}=E_{\text {cell }}^{\circ}+\frac{0.059}{2} \log \frac{\left[\mathrm{Cu}^{2+}\right]}{\left[\mathrm{Zn}^{2+}\right]} ;$

Thus, $E_{\text {cell }}^{\circ}=E_{O_{P C_{1}-/ \mathrm{Cl}_{2}}^{\circ}}^{\circ}+E_{R P_{\mathrm{MnO}_{4}^{-} / \mathrm{Mn}^{2+}}^{\circ}}$

$$
=-1.40+1.51=0.11 \mathrm{~V} \text { or reaction }

is feasible $\mathrm{MnO}_{4}^{-}$will oxidise $\mathrm{Fe}^{2+}$ to $\mathrm{Fe}^{3+}$
$\mathrm{Mn}^{7+}+5 e \rightarrow \mathrm{Mn}^{2+}$

$$
\begin{aligned}
\therefore E_{\text {cell }}^{\sigma} & =E_{O P_{\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+}}^{\circ}}+E_{\mathrm{MnO}_{4}^{-} / \mathrm{Mn}^{2+}} \\
& =-0.77+1.51 \\
& =0.74 \mathrm{~V} \text { or reaction is feasible }

$$

Thus, $\mathrm{MnO}_{4}^{-}$will not oxidise $\mathrm{Fe}^{2+}$ to $\mathrm{Fe}^{3+}$ in aqueous HCl medium but it will also oxidise $\mathrm{Cl}^{-}$to $\mathrm{Cl}_{2}$. Suitable oxidant should not oxidise $\mathrm{Cl}^{-}$to $\mathrm{Cl}_{2}$ and should only oxidise $\mathrm{Fe}^{2+}$ to $\mathrm{Fe}^{3+}$ in redox titrations.

## 488 (c)

Salt bridge is used to remove or eliminate liquid junction potential arised due to different relative speed of ions of electrolytes at the junction of two electrolytes in an electrochemical cell. Thus, a salt bridge such as KCl is placed in between two electrolytes. A salt used for this purpose should have almost same speeds of its cation and anion.
489 (d)
As $\mathrm{AgnO}_{3}$ is added to solution , KCl will be displaced according to following reaction
$\mathrm{AgNO}_{3}(a q)+\mathrm{KCl}(a q) \rightarrow \mathrm{AgCl}_{(s)}+\mathrm{KNO}_{3}(a q)$
For every mole of KCl displaced from solution, one mole of $\mathrm{KNO}_{3}$ comes in solution resulting in almost constant conductivity. As the end point is reached, added $\mathrm{AgNO}_{3}$ remain in solution increasing ionic concentration, hence conductivity increases.
490 (c)
For the given cell, $M\left|M^{+}\right|\left|X^{-}\right| X$, the cell reaction is derived as follows :
RHS :Reduction: $X+e^{-} \rightarrow X^{-}$...(i)
LHS : Oxidation: $M \rightarrow M^{+}+e^{-} \quad$..(ii)
Add Eqs. (i) an (ii)
$M+X \rightarrow M^{+}+X^{-}$
The cell potential $=-0.11 \mathrm{~V}$
Since, $E_{\text {cell }}=-v e$, the cell reaction derived above is non-spontaneous. In fact, the reverse reaction will occur spontaneously

(ii) Cell reaction is spontaneous when $E_{\text {cell }}$ is positive. In case of $A$ and $B$; oxidation potential of $A=-0.03$ oxidation potential of $B=+0.108$

Because oxidation potential of $B$ is more than $A$ so oxidation of $A$ is not possible. The cell having $A$ as anode and $B$ as cathode is not possible.

Therefore, non-spontaneous cell reaction takes place between $A$ and $B$.

$\mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O}+4 e^{-} \rightarrow 4 \mathrm{OH}^{-}$(cathode reaction)
The overall reaction is

$$
2 \mathrm{Fe}+\mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O} \rightarrow 2 \mathrm{Fe}(\mathrm{OH})_{2}

$\mathrm{Fe}(\mathrm{OH})_{2}$ may be dehydrated to iron oxide FeO , or further oxidized to $\mathrm{Fe}(\mathrm{OH})_{3}$ and then dehydrated to iron rust, $\mathrm{Fe}_{2} \mathrm{O}_{3}$.
584 (b)
$\mathrm{Ag}^{+}+e \rightarrow \mathrm{Ag}$
585 (b)
$E_{O P}^{\circ}$ of $\mathrm{Fe}>E_{O P}^{\circ}$ of Cu ;
Thus, Fe gets oxidised or $\mathrm{Fe} \rightarrow \mathrm{Fe}^{2+}+2 e$;

$$
\mathrm{Cu}^{2+}+2 e \rightarrow \mathrm{Cu}
$$

586 (a)
Because, barring Ag, other come after the Fe in electrochemical series

$E_{\text {anode }}=-\frac{R T}{2 F} \ln \frac{\left[\mathrm{H}^{+}\right]^{2}}{p_{1}}$
$E_{\text {cell }}=E_{\text {anode }}+E_{\text {cathode }}$
$=-\frac{R T}{2 F} \ln \frac{\left[\mathrm{H}^{+}\right]^{2}}{p_{1}}-\frac{R T}{2 F} \ln \frac{p_{2}}{\left[\mathrm{H}^{+}\right]^{2}}$
$=-\frac{R T}{2 F} \ln \frac{p_{2}}{p_{1}}=\frac{R T}{2 F} \ln \frac{p_{1}}{p_{2}}$
595 (b)
Weight of Ag required $=80 \times 5 \times 10^{-3} \times$ $1.05(\mathrm{wt} .=v \times d)$

$$
\begin{array}{cc} 
& =0.42 \mathrm{~g} \\
\because & W=\frac{E i t}{96500} \\
\therefore & 0.42=\frac{108 \times 3 \times t}{96500} \\
\therefore & t=125 \mathrm{sec}
\end{array}
$$

596 (c)
$2 \mathrm{H}^{+}+2 e \rightarrow \mathrm{H}_{2}$
(cathode)

$$
2 \mathrm{OH}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+(1 / 2) \mathrm{O}_{2}+2 e \quad \text { (Anode) }
$$

597 (b)
$W=Z \times i \times t$
$\therefore W=0.0011180 \times 0.5 \times 200=0.11180 \mathrm{~g}$
598 (c)
Zn is coated to protect iron from rusting.
599 (c)

600 (b)
$\mathrm{C}_{5} \mathrm{H}_{12}+8 \mathrm{O}_{2} \rightarrow 5 \mathrm{CO}_{2}+6 \mathrm{H}_{2} \mathrm{O}$
$\Delta G^{\circ}=5 \times G^{\circ} \mathrm{CO}_{2}+6 \times G^{\circ} \mathrm{H}_{2} \mathrm{O}-G_{\mathrm{C}_{5} \mathrm{H}_{12}}^{\circ}-8 \times G_{O_{2}}^{\circ}$
$=5 \times(-394.4)+6 \times(-237.2)+8.2$
$=-3387 \mathrm{~kJ}$
$\Delta G^{\circ}=n E^{\circ} F$
$3387 \times 10^{3}=32 \times E^{\circ} \times 96500\left[\left(\mathrm{C}^{-2.4}\right)_{5} \rightarrow\right.$ $\left.5\left(\mathrm{C}^{4+}\right)+32 e\right]$
$\therefore E^{\circ}=1.0968 \mathrm{~V} \quad n=32$
601 (c)
Hydrolysis of water can be represented by the following equations
$2 \mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{O}_{2}+4 \mathrm{H}^{+}+4 e^{-}$
$\because 4$ Faraday of charge liberate $\mathrm{O}_{2}=32 \mathrm{~g}$
$\therefore 1$ Faraday of charge liberate $\mathrm{O}_{2}=\frac{32}{4} \mathrm{~g}$

$$
=8 \mathrm{~g}
$$

602 (a)
Given, $\frac{l}{a}=0.5 \mathrm{~cm}^{-1}$

$$
\begin{aligned}
& R=50 \Omega \\
& N=1.0
\end{aligned}
$$

Specific conductance $(\kappa)=\frac{1}{\rho}=\frac{l}{R \cdot a}=\frac{0.5}{50}$
$\Lambda=\kappa \times \frac{1000}{N}$
$=\frac{0.5}{50} \times \frac{1000}{0.1}$
$=10 \Omega^{-1} \mathrm{~cm}^{2} \mathrm{~g} \mathrm{eq}^{-1}$
603 (d)
The increasing order of deposition of cations at the cathode is

$$
\begin{gathered}
\mathrm{Cu}^{2+}<\mathrm{Ag}^{+}<\mathrm{Au}^{3+} \\
E \propto Z \\
\mathrm{Ag}^{+}+e^{-} \rightarrow \mathrm{Ag} \\
\mathrm{Cu}^{2+}+2 e^{-} \rightarrow \mathrm{Cu} \\
\mathrm{Au}^{3+}+3 e^{-} \rightarrow \mathrm{Au}
\end{gathered}
$$

3 Faradays liberate 1 mole of $\mathrm{Au}, 3$ moles of Ag and $3 / 2$ moles of Cu . Thus, molar ratio of $\mathrm{Ag}: \mathrm{Cu}$ :
Au is $3: 3 / 2: 1$ or $6: 3: 2$.
604 (a)

$$
\begin{aligned}
E_{\mathrm{cell}}^{\circ}= & E_{O P_{\mathrm{Mg}}}^{\circ}+E_{R P_{\mathrm{Cu}}}^{\circ} \\
& =2.37+0.34=2.71 \mathrm{~V}
\end{aligned}
$$

605 (b)
Given,
$\mathrm{Zn}^{2+} \rightarrow \mathrm{Zn}, \quad E^{\circ}=-0.76 \mathrm{~V}$
$\mathrm{Cu}^{2+} \rightarrow \mathrm{Cu}, \quad E^{\circ}=0.34 \mathrm{~V}$
$\mathrm{Ag}^{+} \rightarrow \mathrm{Ag}, \quad E^{\circ}=0.8 \mathrm{~V}$
Cell reaction of (I) is
$\mathrm{Zn}+\mathrm{Cu}^{2+} \rightarrow \mathrm{Zn}^{2+}+\mathrm{Cu}$
$E_{\text {cell }}^{\circ}=E_{\text {oxidation }}+E_{\text {reduction }}$

$$
=+0.76+0.34
$$

$$
=+1.10 \mathrm{~V}
$$

Cell reaction of (II) is

$$
\begin{aligned}
\mathrm{Zn} & +\mathrm{Ag}^{+} \rightarrow \mathrm{Zn}^{2+}+\mathrm{Ag} \\
E_{\text {cell }}^{\circ} & =0.76+0.8 \\
& =+1.56 \mathrm{~V}
\end{aligned}
$$

Cell reaction of (III) is
$\mathrm{Cu}+\mathrm{Ag}^{+} \rightarrow \mathrm{Cu}^{2+}+\mathrm{Ag}$
$E_{\text {cell }}^{\circ}=-0.34+0.8$

$$
=+0.46
$$

So, the correct order of $E_{\text {cell }}^{\circ}$ of these cell is II $>$ I $>$ III.
606 (c)

The equivalent conductance of strong electrolyte is increased by dilution, because its value is equal to the multiple of $K_{v}$ and the volume of solution. By making dilution the volume of solution increases which also increase the value of equivalent conductivity.
607 (b)

608 (c)
In this reaction,

$\mathrm{EMF}=E_{\text {cathod }}-E_{\text {anode }}$
$=-0.41-(-0.76)$
$=+0.35 \mathrm{~V}$

## 609 (a)

$\mathrm{H}_{2}$ is anode because oxidation takes place. Cu is cathode because reduction takes place

610 (b)
Solid NaCl does not conduct electricity due to absence of free ions.
611 (b)

612 (d)
$E_{\text {cell }}=E_{\text {cell }}^{\circ}+\frac{0.059}{2} \log \frac{\left[\mathrm{Ni}^{2+}\right]}{\left[\mathrm{Zn}^{2+}\right]}$
$\therefore 0.5105=E_{\text {cell }}^{\circ}+\frac{0.059}{2} \log \frac{1}{1}$ or $E_{\text {cell }}^{\circ}=0.5105 \mathrm{~V}$
613 (a)

614 (a)
Wt. of Ag deposited $=$ eq. wt. of $\mathrm{Ag}=108 \mathrm{~g}$
Wt . of Ni deposited $=\mathrm{eQ}$. wt. of $\mathrm{Ni}=29.5 \mathrm{~g}$
Wt. of Cr deposited $=$ eq. wt. of $\mathrm{Cr}=17.3 \mathrm{~g}$
615 (a)
The correct relation of $E_{\text {cell }}^{\circ}$ with free energy of cell reaction and equilibrium constant are as follows

$$
\Delta G^{\circ}=n F E_{\mathrm{cell}}^{\circ}
$$

and $\Delta G^{\circ}=-2.303 R T \log K_{\text {eq }}$
616 (a)
Anode: $\mathrm{Fe}(s)+2 \mathrm{OH}^{-} \rightarrow \mathrm{FeO}(s)+\mathrm{H}_{2} \mathrm{O}(l)+2 e$ Cathode : $\mathrm{Ni}_{2} \mathrm{O}_{3}+\mathrm{H}_{2} \mathrm{O}(l)+2 e \rightarrow 2 \mathrm{NiO}(s)+$ $2 \mathrm{OH}^{-}$
$E_{\text {cell }}=E_{O P_{\mathrm{Fe}} / \mathrm{FeO}}^{\circ}-\frac{0.059}{2} \log _{10} \frac{\left[\mathrm{H}_{2} \mathrm{O}\right]}{\left[\mathrm{OH}^{-}\right]^{2}}$

$$
\begin{aligned}
& +E_{R P_{\mathrm{Ni}_{2} \mathrm{O}_{3} / \mathrm{NiO}}}^{\circ} \\
& +\frac{0.059}{2} \log _{10} \frac{\left[\mathrm{H}_{2} \mathrm{O}\right]}{\left[O \mathrm{H}^{-}\right]^{2}}
\end{aligned}
$$

$E_{\text {cell }}=E_{O P_{\mathrm{Fe}} / \mathrm{FeO}}^{\circ}+E_{R P_{\mathrm{Ni}_{2} \mathrm{O}_{3} / \mathrm{NiO}}}^{\circ}$
617 (b)
$K_{a}=c \alpha^{2}$ for weak acid;
$\mathrm{H} A \rightleftharpoons \mathrm{H}^{+}+A^{-}$
618 (d)
C is also calomel electrode.
619 (c)
$\mathrm{CuSO}_{4} \rightleftharpoons \mathrm{Cu}^{2+}+\mathrm{SO}_{4}^{2-}$
At cathode $\mathrm{Cu}^{2+}(a q)+2 e^{-} \rightarrow \mathrm{Cu}(s)$
At anode $2 \mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(a q)+4 e^{-}$
Thus, for the production of one mole of copper
from copper sulphate 2 F of electricity is required.
620 (a)
Eq. of $\mathrm{Al}=$ Eq. of Ag
$\therefore \frac{W_{\mathrm{Al}}}{9}=\frac{W_{\mathrm{Ag}}}{108} \quad$ or $\quad \frac{W_{\mathrm{Al}}}{W_{\mathrm{Ag}}}=\frac{9}{108}$
621 (d)
$W \propto E$; if $Q=$ constant.
622 (a)
From Asolution of $\mathrm{CuSO}_{4}, \mathrm{Cu}$ can be recovered by
Fe metal. Because Fe is more reactive than Cu , it replace Cu easily.
623 (d)
Large negative RP or more positive oxidation potential and thus, more is the tendency to get oxidized.
624 (c)
According to Faraday's second law of electrolysis, we have

$$
\begin{aligned}
& \frac{w_{1}}{w_{2}} & =\frac{E_{1}}{E_{2}} \\
\therefore & \frac{1.08}{x} & =\frac{108}{1}
\end{aligned}
$$

$\therefore$ Weight of hydrogen $(x)=0.01 \mathrm{~g}$
Hence, the volume of hydrogen at

$$
\mathrm{STP}=\frac{22400 \times 0.01}{2}=112 \mathrm{~cm}^{3}
$$

625 (d)
By Nernst equation,
$E_{\text {cell }}=E_{\text {cell }}^{\circ}-\frac{2.303 R T}{n F} \log _{10} K$
At equilibrium $E_{\text {cell }}=0$

Given that,
$\therefore R=8.315 \mathrm{JK}^{-1} \mathrm{~mol}^{-1}$
$T=25^{\circ} \mathrm{C}+273=298 \mathrm{~K}$
$F=96500 C$ and $n=2$
$\therefore \quad E_{\text {cell }}^{\circ}=\frac{2.303 \times 8.314 \times 298}{2 \times 96500} \log _{10} K$

$$
=\frac{0.0591}{2} \log _{10} K
$$

$\because$ Given that $E_{\text {cell }}^{\circ}=0.295 \mathrm{~V}$
$\therefore \quad 0.295=\frac{0.0591}{2} \log _{10} K$
$\log _{10} K=\frac{0.295 \times 2}{0.0591}=10$
$\log _{10} K=$ antilog 10
$K=1 \times 10^{10}$
626 (a)
Follow $E_{O P}^{\circ}$ values in electrochemical series.
627 (c)

& =91.0+426.2-126.5 \\
& =390.7 S \mathrm{~cm}^{2} \mathrm{~mol}^{-1}
\end{aligned}
$$

628 (a)
Fe is more electropositive than copper
Hence, $\mathrm{Cu}^{2+}$ can oxidize Fe

Eq. of $\mathrm{Al}=$ Eq. of Na ;
$\therefore \frac{1.8}{27 / 3}=\frac{W}{23}$
$\therefore W_{N a}=4.6 \mathrm{~g}$
630 (a)
$X$ coulomb deposits 1 mole Al or 3 eq. of Al and thus, it will deposit 3 mole or 3 eq. of Ag is monovalent,
$\left[\therefore \frac{W}{E}(\right.$ for Ag$)=\frac{W}{E}($ for Al$\left.)\right]$

## 631 (d)

During electrolysis of $\mathrm{CuSO}_{4}, \mathrm{Cu}^{2+}$ gets discharged at cathode and $\mathrm{OH}^{-}$at anode. Thus, solution becomes acidic due to excess of $\mathrm{H}^{+}$and $\mathrm{SO}_{4}^{2-}$ or $\mathrm{H}_{2} \mathrm{SO}_{4}$

## : HINTS AND SOLUTIONS :

1 (d)
On doubling the concentration. The emf will remain unchanged because $\left[\mathrm{Zn}^{2+}\right] /\left[\mathrm{Cu}^{2+}\right]$ will remain same.

2 (a)
According to Kohlrausch law, 'Limiting molar conductivity of an electrolyte can be represented as the sum of the individuals contributions of the anion and cation of the electrolyte.

3 (b)
In a galvanic cell, anode is the negative terminal and the reaction occurring here is oxidation. Cathode is the positive terminal and the reaction occurring here is reduction. Electrons move from anode to cathode in the external circuit

4 (a)
Zinc metal which has a more negative electrode potential than iron will provide electrons in preference of the iron, and therefore corroids first. Only when all the zinc has been oxidized, the iron start to rust

5 (b)
$\mathrm{Zn}(\mathrm{I})+\mathrm{Hg}(\mathrm{s}) \rightarrow \mathrm{ZnO9}(\mathrm{~s})+\mathrm{Hg}(\mathrm{I})$
The cell potential remains constant during its life as the overall reaction does not involve any ion in solution whose concentration change during its life time.

## 6 (a)

Na metal is not produced at the cathode (instead $\mathrm{H}_{2}$ is formed) because water contains $\mathrm{H}_{3} \mathrm{O}^{+}$ions or $\mathrm{H}^{+}$ions which are stronger oxidizing agent than $\mathrm{Na}^{+}$, and are therefore more easily reduced

7
(d)

Copper is present below hydrogen, therefore
hydrogen from HCl can't be liberated by treating it with copper
(c)
$i=96.5 \mathrm{~A}, \mathrm{t}=100 \mathrm{~s}$
$w=10.8$
$Q=i t$
$Q=96.5 \times 100=9650 C$
$\because 96500$ C deposited wt. of $\mathrm{Ag}=108 \mathrm{~g}$
$\therefore 9650 \mathrm{C}$ deposited wt. of $\mathrm{Ag}=\frac{108 \times 9650}{96500}$
So, Assertion is true but Reason is false. Reason is false because mass of substance deposited is directly proportional to the quantity of electricity.

Leads storage battery is a secondary cell because after use it can be reacharged by passing current through it in opposite direction so that it can be used again.

11 (d)
The specific conductivity decreases while equivalent and molar conductivities increase with dilution

[^0]:    a) The electrons will flow from $B$ to $A$ when connection is made
    b) The e.m.f. of the cell will be 0.56 V
